The user can create a virtual partition on the hard drive. The virtual partition contains a volume name, a volume label, a size, a drive letter, a volume flags, a file allocation table (FAT), a directory allocation table (DAT), a backup boot sector and a backup boot sector log, as well as the partition size, the partition type, the partition values, the partition boot code, and the boot code type. Shared storage space is an essential part of running a network, and in most cases this is done by networking hard disks. With the help of a shared storage space you can do numerous things, including migrating data to a central location and accessing the data from anywhere. If your office network features multiple computers, you can use shared storage space in several ways, depending on the configuration you have in place and what you need to do with it. There are many different types of shared storage space available, and which one is the best for you will depend on your needs and how many computers are involved. Shared storage space is mostly made of two or more hard disks linked to a network. The data that resides on the disks is accessible from any computer that has a connection to the network, and the data is stored on the hard disks in a centralized manner. In most cases this data is backed up and is constantly available for access, but you can also backup the data yourself. The advantage of this kind of storage space is that all the data is available to all computers on the network, and the data can be accessed quickly as it is networked. The disadvantage, however, is that you need to provide the hard disks for everyone on the network, and then you also need to make sure that the data is backed up for everyone as well. If a hard disk fails it can render any data on that hard disk inaccessible. There are two types of shared storage space: network and local. Local shared storage space is a direct copy of data on a hard disk or a CD that is available in the same local area. With this kind of shared storage space you can use it for personal data that is not backed up, for example pictures, music, and so on. To make sure that you have access to the data you need, you must either leave the computer alone or have a portable version of the data in a local hard disk. The problem with this kind of shared storage space is that you cannot access the data from multiple computers at the same time. Modern operating systems come with a built-in recovery system that enables you to perform file system recovery if needed. Most often this recovery process can be done directly from the computer you are working with, but there are several ways to do this and the most reliable one is to do so via the Internet. The following steps will guide you through the process of recovering a Windows XP computer in case of a corrupted file system. Step 1. Restart the
