Gjej Password Te Facebook

I tried the following but did not work: `data-ng-options="option.pass.tag as option.pass.value for option in webdata.selectmenu.data"` A: By looking at the source code, you can see that you're not able to access the pass value as they're stored in a JSON structure: `{{ option.pass.value }}` If you open the `main.js` of the plugin, you can see the structure of the JSON object:

```
var webdata = { selectmenu: { selectmenu: { selectmenu: { selectmenu: [...], }, }, }, };
```

This being said, a possible solution is to create your own JSON by combining all the necessary options in one array and setting the password array: `data-ng-options="item as (item.pass = (item.pass.value || '') + item.name || '') for item in data.options"` In this way you will have the ability to access the complete options data because the `option.pass.value` will be: `['Pass', 'Login', 'Email', 'Phone', 'Password'].join('|')` Here a Fiddle playing with the plugin If you need the plugin

you can download it here: {

The content of the variable has a specific structure - the text is a HTML code which has a string of other text elements separated by special markers. So to use a regex on the variable would be a bad idea. Note that if the string contains new line and tab characters, you'll need to trim them before applying your regex. The following is basically the same as the snippet above, but it does not trim the strings and it will match the whole string

if it contains new lines or tabs.
So you could alter the regex a bit to only match a specific section of the string.

```
import re
data = "
test text "
pat = r'([\^]*)'
```

```
data_match = re.search(pat, data)
print data_match.group(0)
```

However, in the real world, I would advise against using regex for this, and instead make use of dedicated tool or library for that.

Why use regex? Using regex you can have potentially complex strings within your regex pattern, and also have very detailed control over what is matched, including re-writing and manipulating the string using

backreferences. But it is also very open to malicious attacks through string obfuscation - where the string is changed in a way which makes it difficult to see the structure or what is happening. For this reason, you usually can't just match the whole string using regex. Why not use a string parsing library? In practice, for a simple string parsing problem like this, it is much easier to use dedicated tool - instead of re-inventing the wheel. There are lots of string parsing libraries on Python's standard library. I usually use Python's `itertools.groupby` and

```
itertools.takewhile here: from
    itertools import groupby,
    takewhile
def get_match(data):
    elements = ["", "", "", ""]
    for element in elements:
        match = re.findall(element, data)
        if match:
            yield match
```
