I hope this is what you need. See related research by Roche *et al.*, In their article on 'Clinical consequences of the rate and extent of tissue turn-over in breast cancer: how do they correlate with outcome?' Roche *et al*. \[[@B1]\] used immunohistochemical techniques to examine levels of estrogen and progesterone receptors, Her2/neu, c-erbB-2 and Ki67 in sequential sections of 41 breast cancers. Cellularity in stromal tissue was assessed, and stromal-intracellular ratios were calculated. They found that none of the individual parameters correlated with disease-free interval (DFI). However, patients with a high stromal-intracellular ratio (S-I) had a significantly higher risk of tumor relapse and death. The group chose to examine S-I in this study because it had been shown to be a powerful prognostic factor in the recently reported Nottingham study \[[@B2],[@B3]\]. By visual examination of each tumor section, several experts could make an independent assessment of the stromal and intracellular areas in the tissue. In their study, Roche *et al*. \[[@B1]\] examined tumor sections and determined S-I in a similar way. Given that outcome is primarily determined by local tumor extension, not
